Introduction

All transport data set records are 80 bytes in length. If there is not sufficient data to reach 80 bytes, then a record is padded with ASCII blanks to 80 bytes. All integers are stored using IBM-style integer format, and all floating-point numbers are stored using the IBM-style double (truncated if the variable's length is less than 8). (An exception to this is noted later.) See the section "Numeric Data Fields" for information about constructing IBM-style doubles.

All character data is stored in the Windows encoding that is compatible with the SAS session encoding that is used to create the file. For a table of character set compatibility, go to [Encoding and Their Aliases and Encoding Character Set Compatibility](#). On this page, scroll down to the "Encoding Character Set Compatibility" table. The Windows compatible encoding is the first encoding name in each row of the "Encoding names (in SAS)" column.

Record Layout

1. The first header record consists of the following character string, in ASCII:

```
HEADER RECORD*****LIBRARY HEADER RECORD!!!!!!0000000000000000000000000000  
00000
```

2. The first real header record uses the following layout:

```
aaaaaaaaabbbbbbbbccccccddddddeeeeeeee ffffffffffffffff
```

In this record:

- aaaaaaaaa and bbbbbbbb specify 'SAS'.
- cccccccc specifies 'SASLIB'.
- dddddd specifies the version of the SAS(r) System under which the file was created.
- eeeeeeee specifies the operating system that creates the record.
- ffffffffffffff specifies the date and time created, formatted as *ddMMMyy:hh:mm:ss*.

Note that only a 2-digit year appears. If any program needs to read in this 2-digit year, be prepared to deal with dates in the 1900s or the 2000s.

Another way to consider this record is as a C structure:

```
struct REAL_HEADER {  
    char sas_symbol[2][8];  
    char saslib[8];  
    char sasver[8];  
    char sas_os[8];  
    char blanks[24];  
    char sas_create[16];  
};
```

3. Second real header record

```
ddMMMyy:hh:mm:ss
```

In this record, the string is the datetime modified. Most often, the datetime created and datetime modified will

always be the same. Pad with ASCII blanks to 80 bytes. Note that only a 2-digit year appears. If any program needs to read in this 2-digit year, be prepared to deal with dates in the 1900s or the 2000s.

4. Member header records

Both of these records occur for every member in the transport file.

Note the 0140 that appears in the member header record above. This value specifies the size of the variable descriptor (NAMESTR) record that is described later in this document. On the VAX/VMS operating system, the value will be 0136 instead of 0140. This means that the descriptor will be only 136 bytes instead of 140.

5. Member header data

In this member header:

- aaaaaaaaa specifies 'SAS'.
 - bbbbbbbb specifies the data set name.
 - cccccccc is SASDATA (if a SAS data set is being created).
 - dddddddd specifies the version of the SAS System under which the file was created.
 - eeeeeeee specifies the operating system.
 - ffffffffffffff is the datetime created, formatted as in previous headers.

Consider this C structure:

```
struct REAL_HEADER {
    char sas_symbol[8];
    char sas_dsnname[8];
    char sasdata[8];
    char sasver[8];
    char sas_osname[8];
    char blanks[24];
    char sas_create[16];
};
```

The second header record is as follows:

In this record the datetime modified appears using the DATETIME16. format, followed by blanks up to column 33, where aaaaaaaaaaaaaaaaaaaaaaaa corresponds to a blank-padded data set label and bbbbbbbb is the blank-padded data set type. Note that data set labels can be up to 256 characters as of SAS8, but only the first 40 characters are stored in the second header record. Note also that only a 2-digit year appears in the datetime modified value. If any program needs

to read in this 2-digit year, be prepared to deal with dates in the 1900s or the 2000s.

Consider the following C structure:

```
struct SECOND_HEADER {  
    char dtmod_day[2];  
    char dtmod_month[3];  
    char dtmod_year[2];  
    char dtmod_colon1[1];  
    char dtmod_hour[2];  
    char dtmod_colon2[1];  
    char dtmod_minute[2];  
    char dtmod_colon3[1];  
    char dtmod_second[2];  
    char padding[16];  
    char dslabel[40];  
    char dstype[8]  
};
```

6. Namestr header record

One for each member.

```
HEADER RECORD*****NAMESTR HEADER  
RECORD!!!!!!000000xxxx000000000000  
0000000
```

In this header record, xxxx is the number of variables in the data set, displayed with blank-padded numeric characters. For example, for 2 variables, xxxx=0002. xxxx occurs at offset 54 (base 0 as in C languageuse).

7. Namestr records

Each namestr field is 140 bytes long, but the fields are streamed together and broken in 80-byte pieces. If the last byte of the last namestr field does not fall in the last byte of the 80-byte record, the record is padded with ASCII blanks to 80 bytes.

Here is the C structure definition for the namestr record:

```

struct NAMESTR {
    short ntype;           /* VARIABLE TYPE: 1=NUMERIC, 2=CHAR      */
    short nhfun;           /* HASH OF NNAME (always 0)          */
    short nlng;            /* LENGTH OF VARIABLE IN OBSERVATION */
    short nvar0;           /* VARNUM      */
    char8 nname;           /* NAME OF VARIABLE*/
    char40 nlabel;          /* LABEL OF VARIABLE      */
    char8 nform;           /* NAME OF FORMAT   */
    short nfl;              /* FORMAT FIELD LENGTH OR 0      */
    short nfd;              /* FORMAT NUMBER OF DECIMALS   */
    short nfj;              /* 0=LEFT JUSTIFICATION, 1=RIGHT JUST */
    char nfill[2];          /* (UNUSED, FOR ALIGNMENT AND FUTURE) */
    char8 niform;           /* NAME OF INPUT FORMAT   */
    short nifl;              /* INFORMAT LENGTH ATTRIBUTE   */
    short nifd;              /* INFORMAT NUMBER OF DECIMALS */
    long npos;              /* POSITION OF VALUE IN OBSERVATION */
    char rest[52];          /* remaining fields are irrelevant */
};
```

Note that the length given in the last 4 bytes of the member header record indicates the actual number of bytes for the NAMESTR structure. The size of the structure listed above is 140 bytes. Under VAX/VMS, the size will be 136 bytes, meaning that the 'rest' variable may be truncated.

8. Observation header

HEADER RECORD*****OBS HEADER RECORD!!!!!!00000000000000000000000000000000

9. Data records

Data records are streamed in the same way that namestrs are. There is ASCII blank padding at the end of the last record if necessary. There is no special trailing record.

Missing Values

Missing values are written out with the first byte (the exponent) indicating the proper missing values. All subsequent bytes are 0x00. The first byte is:

type	byte
.	0x5f
.	0x2e
.A	0x41
.B	0x42
...	
.Z	0x5a

A Sample Session to Show a Transport Data Set

This session was run on a ASCII-based system to demonstrate the creation and record layout of a transport data set.

```
$ sas606
1? libname xxx sasv5xpt 'xxx.dat';

NOTE: Libref XXX was successfully assigned as follows:
      Engine: XPORT
      Physical Name: xxx.dat
      ...

8? data temp; input x y $ @@; cards;
9> 1 a 2 B . . .a *
10> run;

NOTE: SAS went to a new line when INPUT statement reached past the end
      of a line.

NOTE: The data set WORK.TEMP has 4 observations and 2 variables.

NOTE: The DATA statement used 10 seconds.

NOTE: The DATA statement used 1 seconds cpu time.
11? data temp; set temp;
12? format x date7.; label y='character variable'; run;

NOTE: The data set WORK.TEMP has 4 observations and 2 variables.
NOTE: The DATA statement used 12 seconds.

NOTE: The DATA statement used 2 seconds cpu time.
13? proc print data=temp; format x y ; run;
```

RULE: ---+---1---+---2---+---3---+---4---+---5---+---6---+---7---+---8+

In case you're not familiar with the LIST output from the DATA step, here's a brief explanation:

If the record has any unprintable characters, LIST output generates three lines of output:

1. the record itself, printing everything that's printable and using dots for everything else
 2. the upper nibble of each byte in hex
 3. the lower nibble of each byte in hex.

Consider, then, record 9, which has some printable and unprintable characters:

The first 8 bytes are unprintable, since dots appear. Those first 8 bytes, reading in sequential hex format, would be 00010000 00080001. The next 56 bytes are printable. Then, we have 00070000 00000000. The remaining 8 bytes are ASCII blanks.

Numeric Data Fields

All numeric data fields in the transport file are stored as floating-point numbers.

All floating-point numbers in the file are stored using the IBM mainframe representation. If your application is to read from or write to transportfiles, it will be necessary to convert native floating-point numbers to or from the transport representation.

Most platforms use the IEEE representation for floating-point numbers. Someof these platforms store the floating-point numbers in reversed byte order from other platforms. For the sake of nomenclature, we will call these platforms "big endian" and "little endian" platforms.

A big-endian environment stores integers with the lowest-significant byte at a higher address in memory. Likewise, an IEEE platform is big endian if the first byte of the exponent is stored in a lower address than the first byte of the mantissa. For example, the HP series machines store a floating-point 1 as 3F F0 00 00 00 00 00 00 (the bytes in hex), while an IBM PC stores a 1 as 00 00 00 00 00 00 F0 3F. The bytes are the same, just reversed. Therefore, the HP is considered big endian and the PC is considered little endian.

This is a partial list of the categories of machines on which the SAS System runs:

Operating			
Hardware	Systems	Float Type	Endian
<hr/>			
IBM mainframe	MVS, CMS, VSE	IBM	big
DEC Alpha	AXP/VMS, DEC UNIX	IEEE	little
HP	HP-UX	IEEE	big
Sun	Solaris I,II	IEEE	big
RS/6000	AIX	IEEE	big
IBM PC	Windows, OS/2, IABII	IEEE	little

Not included is VAX, which uses a different floating-point representationthan either IBM mainframe or IEEE.

Provided Subroutines

To assist you in reading and/or writing transport files, we are providing routines to convert from IEEE representation (either big endian or little endian) to transport representation and back again. The source code for these routines is provided at the end of this document. Note that the source code is provided as is, and as a convenience to those needing to read and/or writetransport files. The source code has been tested on HP-UX, DEC UNIX, IBM PC, and MVS.

The routine to use is `cnxptiee`. This routine will convert in either direction, either to or from transport. Its usage is as follows:

```
/*-----*/  
/* rc = cnxptiee(from,fromtype,to,totype); */  
/*  
/* where  
/*  
/* from pointer to a floating point value */  
/* fromtype type of floating point value (see below) */  
/* to pointer to target area */  
/* totype type of target value (see below) */  
/*  
/* floating point types:  
/* 0 native floating point */  
/* 1 IBM mainframe (transport representation) */  
/* 2 Big endian IEEE floating point */  
/* 3 Little endian IEEE floating point */  
/*  
/* rc = cnxptiee(from,0,to,1); native -> transport */  
/* rc = cnxptiee(from,0,to,2); native -> Big endian IEEE */  
/* rc = cnxptiee(from,0,to,3); native -> Little endian IEEE */  
/* rc = cnxptiee(from,1,to,0); transport -> native */  
/* rc = cnxptiee(from,1,to,2); transport -> Big endian IEEE */  
/* rc = cnxptiee(from,1,to,3); transport -> Little endian IEEE */  
/* rc = cnxptiee(from,2,to,0); Big endian IEEE -> native */  
/* rc = cnxptiee(from,2,to,1); Big endian IEEE -> transport */  
/* rc = cnxptiee(from,2,to,3); Big endian IEEE -> Little endian IEEE */  
/* rc = cnxptiee(from,3,to,0); Little endian IEEE -> native */  
/* rc = cnxptiee(from,3,to,1); Little endian IEEE -> transport */  
/* rc = cnxptiee(from,3,to,2); Little endian IEEE -> Big endian IEEE */  
/*-----*/
```

The "native" representation is whatever is appropriate for the host machine. Most likely you will be using that mode.

The `testieee.c` routine is supplied here to demonstrate how the `cnxptiee` is used. It is also useful to ensure that the `cnxptiee` routine works in your environment.

Note that there are several symbols that can be defined when compiling the `ieee.c` file. These symbols are `FLOATREP`, `BIG_ENDIAN`, and `LITTLE_ENDIAN`.

`FLOATREP` should be set to one of the following strings:

```
-- CN_TYPE_IIEEEB Big endian IEEE  
-- CN_TYPE_IIEEEL Little endian IEEE  
-- CN_TYPE_XPORT Transport format (for example, IBM)
```

If `BIG_ENDIAN` is defined, it is assumed that the platform is big endian. If `LITTLE_ENDIAN` is defined, it is assumed that the platform is little endian. Do not define both of them.

If `FLOATREP` is not defined, the proper value is determined at run time. Although this works, it incurs additional overhead that can increase CPU time with large files. Use the `FLOATREP` symbol to improve efficiency. Likewise, if neither `BIG_ENDIAN` nor `LITTLE_ENDIAN` is defined, the proper orientation is determined at run time. It is much more efficient to supply the proper definition at compile time.

As an example, consider this command on HP-UX:

```
cc testieee.c ieee.c -DFLOATREP=CN_TYPE_IEEEB -DBIG_ENDIAN
```

Also consider the corresponding command on DEC UNIX:

```
cc testieee.c ieee.c -DFLOATREP=CN_TYPE_IEEEL -DLITTLE_ENDIAN
```

Here is the correct output from the testieee run:

```
Native -> Big endian IEEE match count = 4 (should be 4).  
Native -> Little endian IEEE match count = 4 (should be 4).  
Native -> Transport match count = 4 (should be 4).  
Transport -> Big endian IEEE match count = 4 (should be 4).  
Transport -> Little endian IEEE match count = 4 (should be 4).  
Transport -> Native match count = 4 (should be 4).  
Big endian IEEE -> Little endian IEEE match count = 4 (should be 4).  
Big endian IEEE -> Transport match count = 4 (should be 4).  
Big endian IEEE -> Native match count = 4 (should be 4).  
Little endian IEEE -> Big endian IEEE match count = 4 (should be 4).  
Little endian IEEE -> Transport match count = 4 (should be 4).  
Little endian IEEE -> Native match count = 4 (should be 4).
```

Here is the source code for the test program, testieee.c

```
-----testieee.c-----  
  
#define CN_TYPE_NATIVE 0  
  
#define CN_TYPE_XPORT 1  
#define CN_TYPE_IEEEB 2

/* Translate IEEE floating point number into IBM format float */
/*
/* IEEE format:
/*
/* 6 5 0
/* 3 1 0
/*
/* SEEEEEEEMMM ....... MMMM
/*
/* Sign bit, 11 bit exponent, 52 fraction. Exponent is excess
/* 1023. The fraction is multiplied by a power of 2 of the
/* actual exponent. Normalized floating point numbers are
/* represented with the binary point immediately to the left
/* of the fraction with an implied "1" to the left of the
/* binary point.
/*
/* IBM format:
/*

```

```

/* 6 5 0 */  

/* 3 5 0 */  

/* */  

/* SEEEEEMMM ..... MMMM */  

/* */  

/* Sign bit, 7 bit exponent, 56 bit fraction. Exponent is */  

/* excess 64. The fraction is multiplied by a power of 16 of */  

/* of the actual exponent. Normalized floating point numbers */  

/* are presented with the radix point immediately to the left */  

/* of the high order hex fraction digit. */  

/* */  

/* How do you translate from local to IBM format? */  

/* */  

/* The ieee format gives you a number that has a power of 2 */  

/* exponent and a fraction of the form "1.<fraction bits>". */  

/* The first step is to get that "1" bit back into the */  

/* fraction. Right shift it down 1 position, set the high */  

/* order bit and reduce the binary exponent by 1. Now we have */  

/* a fraction that looks like ".1<fraction bits>" and it's */  

/* ready to be shoved into ibm format. The ibm fraction has 4 */  

/* more bits than the ieee, the ieee fraction must therefore */  

/* be shifted left 4 positions before moving it in. We must */  

/* also correct the fraction bits to account for the loss of 2 */  

/* bits when converting from a binary exponent to a hex one */  

/* (>> 2). We must shift the fraction left for 0, 1, 2, or 3 */  

/* positions to maintain the proper magnitude. Doing */  

/* conversion this way would tend to lose bits in the fraction */  

/* which is not desirable or necessary if we cheat a bit. */  

/* First of all, we know that we are going to have to shift */  

/* the ieee fraction left 4 places to put it in the right */  

/* position; we won't do that, we'll just leave it where it is */  

/* and increment the ibm exponent by one, this will have the */  

/* same effect and we won't have to do any shifting. Now, */  

/* since we have 4 bits in front of the fraction to work with, */  

/* we won't lose any bits. We set the bit to the left of the */  

/* fraction which is the implicit "1" in the ieee fraction. We */  

/* then adjust the fraction to account for the loss of bits */  

/* when going to a hex exponent. This adjustment will never */  

/* involve shifting by more than 3 positions so no bits are */
